

# CMPSC 100 SPRING 2021

If we're going to start another week,  
we might as well do it while we're here

# WELCOME & COURSE INFORMATION

- For **Group B** viewers: reminder that there's no class on Wednesday
  - Welcome **Group B** viewers
- The assignment for the week is posted to #assignments
  - Recall that you need to click the link to accept and clone it
- Quiz is posted to course schedule
- First round of grades is on the course Canvas

Essentially a boolean

# BOOLEAN DATA TYPE

- Booleans track values of `True` and `False` (capitalization matters)
- These are not `strings`; they are actual values
- Booleans are used to help make decisions
  - This is especially true of their use in something called a `condition`

# IF YOU'RE AFRAID OF THE DARK...

```
# if it's on  
light_switch = True  
  
# if it's off  
light_switch = False
```

# IF STATEMENTS

```
if light_switch == True:  
    print("Light's on!")
```

(Equivalent to asking "is this True?")

```
if light_switch:  
    print("Light's on!")
```

(Notice the indent - it's important)

# IF STATEMENTS

General form:

if CONDITION:  Read the : as “then”  
    # do something

# IF STATEMENTS

```
if light_switch:
    # killing the planet, one set of dinosaur remains at a time
    print("Light's on!")
else:
    # oh, you're a regular Captain Planet, now
    print("Light's off!")
```

# IF STATEMENTS

```
if light_switch:
    # if light_switch True
elif not light_switch:
    # if light_switch False
    print("Light's off!")
else:
    # any other conceivable value
    print("Must not have power.")
```

## WHILE WE'RE HERE...

```
power_on = True
```

```
while power_on:
```

```
    choice = input("Turn the switch off? [Y]/[N]? ")
```

```
        if choice == "Y":
```

```
            power_on = False
```

Again, notice the indent:  
it demonstrates what  
"belongs" a while or if  
"block"

F  
L  
O  
W  
  
O  
F  
  
C  
O  
N  
T  
R  
O  
L

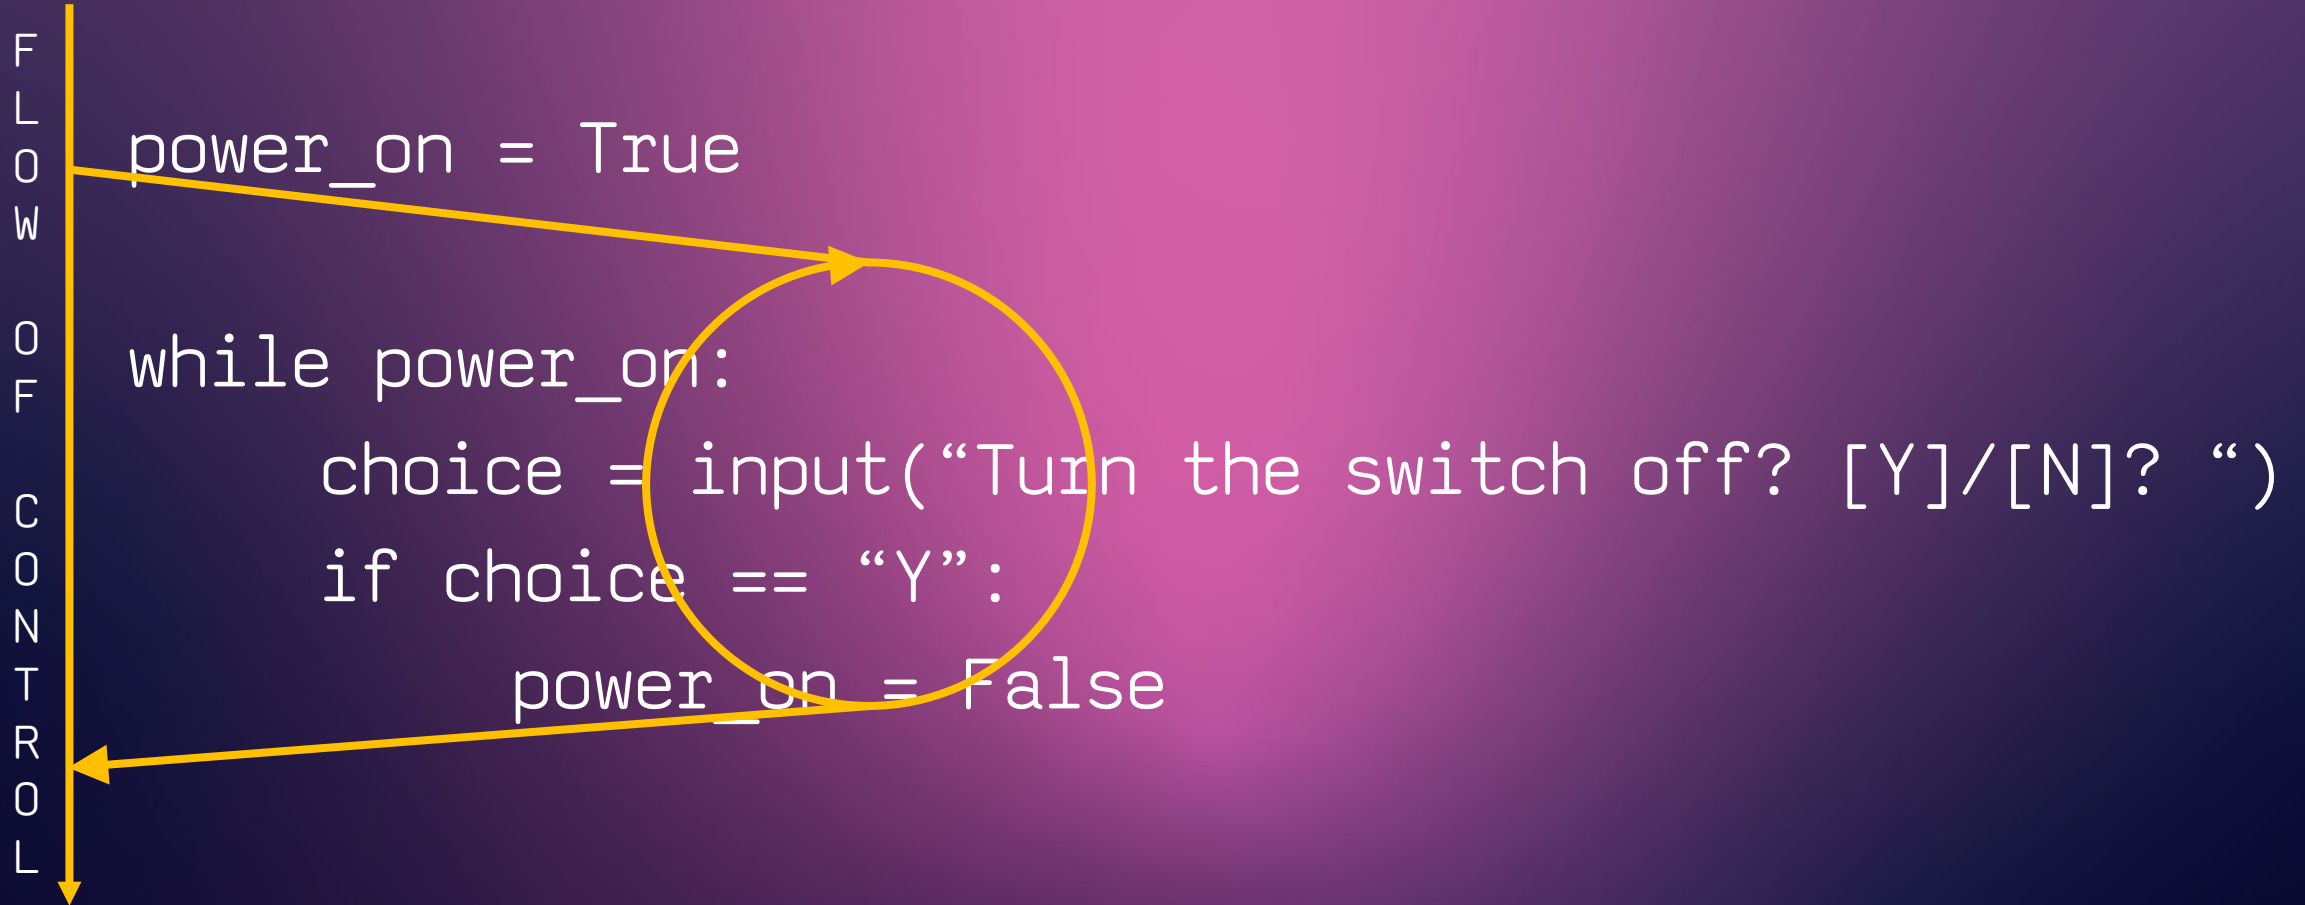

```
power_on = True
```

```
while power_on:
```

```
    choice = input("Turn the switch off? [Y]/[N]? ")
```

```
    if choice == "Y":
```

```
        power_on = False
```

## while

Model behaviors -- operations to conduct while a condition is true

Executes all “member” statements until a condition is no longer true

Conditions can be simple (while light\_switch == True) or complex (while light\_switch == True and power == on)

Can be used to “count” by setting up a “sentinel variable”:

```
t = 10
```

```
While t > 0:  
    print(t)  
    t -= 1
```
